LESSON

You can use the idea of finite differences to decide whether the data can be modeled by a linear function, a quadratic function, or neither.

EXAMPLE 1 Find a Model for Data Given in a Table
The data in the table represent five points on the graph of a function.

| $x$ | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{y}$ | 2 | 6 | 12 | 20 | 30 |

## Solution

Begin by writing the $y$-values from the table horizontally on a piece of paper. Subtract the first $y$-value, 2, from the second $y$ value, 6 , and write the result (4) below and between the two $y$-values. Then subtract the second $y$-value, 6 , from the third $y$-value, 12 , and write the result (6) below and between these two $y$-values. Repeat the process for the remaining $y$-values.

The numbers $4,6,8$, and 10 in the second row are called the first finite differences. If each number in this row were the same number, the points in the table would represent a linear function, but they are not the same. So repeat the process, this time using the first finite differences.

This numbers in the third row are called the second finite differences. Notice that these differences are the same. When the second finite differences are the same, the data in the table can be modeled by a quadratic function.

If the first and second differences both fail to be the same, the data in the table cannot be modeled using either a linear or quadratic function.

## Determine whether the data in the table can be modeled by a linear function, a quadratic function, or neither.

1. 

| $x$ | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $y$ | 0 | 1 | 4 | 9 | 1 |

2. 

| $x$ | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{y}$ | 1 | -1 | -3 | -5 | -7 |

3. 

| $x$ | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{y}$ | 1 | 9 | 27 | 81 | 243 |
